Abstract

Postoperative anal pain is one of the main adverse effects of surgical treatment of benign anorectal diseases and remains a distressing problem, for both patients and physicians. Postoperative pain control is important yet it remains an unresolved issue which causes patient dissatisfaction and negatively impact quality of life. This review article studied the analgesic effect of topical and oral metronidazole after benign anorectal surgery. Seven studies used oral metronidazole and six used topical metronidazole. The studies showed that post operative pain score of patients who had metronidazole by either route was significantly less than those in comparison groups. The pain score decreased at all the time points for both oral and topical metronidazole. Overall, the analgesic effect of oral metronidazole was inconsistent among published studies. When topical and oral metronidazole were compared the post operative pain score and analgesic consumption were lower in topical metronidazole than the oral group

INTRODUCTION

Anal surgeries are among the most commonly performed operations all over the world. The most common fear of patients undergoing such surgeries is the postoperative pain which can be quite annoying and may delay return to daily activities (1). Post-anal surgery pain is multifactorial; internal anal sphincter spasm, inflammation and superadded bacterial contamination of the operative site have a role (2-4). Indeed, the pain intensity has individual variation yet it's related to the extent of excision, defective wound healing and superadded infections (5, 6).

The use of new energy devices (Harmonic Scalpel and LigaSure) has been associated with less post-operative pain but they are expensive if compared with the conventional diathermy techniques (7, 8). Many pharmacologic agents (with different mechanisms of action) have been tried to decrease the post-operative pain as anesthetics, internal sphincter relaxants, opioid and non-opioid analgesics, flavonoids, sucralfate & antibiotics (9). Topical preparations are preferred over other dosage forms because of better bioavailability and fewer incidence of side effects (10). Metronidazole is a nitroimidazole member that acts against anaerobic pathogens & protozoa and is used extensively because it is safe, cheap, efficacious, with relatively little side effects (11).

Systemic and topical agents used for pain relief after anal surgery

The use of several medications during or after anal surgery for the reduction of postoperative pain has been extensively discussed in the literature.

Analgesics and anesthetic medications: Analgesics such as ketorolac can achieve adequate control of post-hemorrhoidectomy pain, whether

administered locally or systemically. Injection of ketorolac directly into the IAS fibers serves to inhibit its spasm by suppressing the prostaglandin formation in addition to its anti-inflammatory effect (12). O'Donovan and colleagues (13) reported that combined oral administration and local injection of ketorolac after hemorrhoidectomy achieved equivalent pain control to that of the narcotics group.

Local infiltration of long-acting anesthetic as bupivacaine around the skin of the anal verge can also decrease the severity of post hemorrhoidectomy pain. Haas et al. have compared among the local infiltration of Liposome Bupivacaine (LB) and bupivacaine HCl post hemorrhoidectomy and concluded that LB resulted in significantly decreased postoperative pain compared with bupivacaine HCl (14).

Sucralfate and cholestyramine: Sucralfate decreases pain post hemorrhoidectomy by promoting wound healing due to its inhibitory actions on the degradation of fibroblast and to its angiogenic actions (12). Gupta et al. found that topical sucralfate significantly reduced pain after hemorrhoidectomy up to two weeks postoperatively and provided quicker wound healing in comparison to that of a placebo group (15). The results of Gupta and colleagues were repeated by another double-blind randomized study which noticed that sucralfate ointment.

Chemical sphincterotomy: the IAS spasm was thought to be the major factor contributing to pain after hemorrhoidectomy; topical medications that induce direct relaxation of the IAS or what is called chemical sphincterotomy were tried to decrease the degree of pain after hemorrhoidectomy (12, 16). A literature review by Siddiqui and colleagues

recognized three different groups of these medications: Glyceryl Trinitrate (GTN), calcium channel blockers, and botulinum toxin. The study found that the three groups were effective in pain control up to one week after hemorrhoidectomy compared to a placebo group (17).

Few trials assessed calcium channel blockers in reduction of pain after hemorrhoidectomy. Three placebo-controlled randomized trials (18) used topical diltiazem 2%, whereas one randomized study (19) used nifedipine 0.3%. While both diltiazem and nifedipine provided significantly less pain at 7 days after hemorrhoidectomy, higher rate of complications was reported, including fecal incontinence that was 2.4% after the use of Nifedipine 0.3% combined with lidocaine 1.5%.

The role of metronidazole in pain relief after anorectal surgery

Metronidazole has been recognized to decrease pain after hemorrhoidectomy when administered systemically. Metronidazole is reported to relieve post-hemorrhoidectomy pain because of its antimicrobial action that reduces the bacterial colonization at the surgical sites, in addition to its anti-inflammatory effects as well. The pain-relieving effect of systemic metronidazole is debatable as Solorio-López et al (20) proved that oral administration of metronidazole 500mg can effectively reduce pain after hemorrhoidectomy compared with a placebo. In contrast, Khan and colleagues (21) concluded that prophylactic antibiotics, including metronidazole, have no tangible role in pain relief after open hemorrhoidectomy. Additionally, Balfour et al (22) disclosed that

the systemic application of metronidazole 400mg three times per day after closed hemorrhoidectomy did not reduce the postoperative pain.

Topical metronidazole ointment has the privilege of higher tissue concentration along with less systemic side effect than the oral medication. In placebo-controlled randomized study, Ala and affiliates (23) found that topical application of metronidazole 10% significantly reduced discomfort after hemorrhoidectomy up to 14 days, and alleviated postoperative pain during defecation as compared to the placebo group. Nicholson and Armstrong (24) also reported significant reduction of post-hemorrhoidectomy discomfort and edema after using topical metronidazole 10%.

Another topical antimicrobial that was devised for the reduction of post-hemorrhoidectomy pain is triclosan which was investigated in a multi-center double blind randomized trial (25) and was found to improve the control of post-operative symptoms, including pain, and wound healing compared to sodium hypochlorite.

Table 1 summarizes the outcome of different trials that examined the impact of topical and oral metronidazole on pain relief after anorectal surgery.

Conclusions

Topical metronidazole appears to have a more consistent analgesic effect after surgery for benign anorectal condition, namely hemorrhoidectomy, when compared to oral metronidazole.

Table 1. Summary of studies that assessed the analgesic effect of topical and oral metronidazole:

Study	operation	Metronidazole	Comparator	Conclusion
Carapeti et al., 1998(29)	Haemorrhoidectomy	Oral	Placebo	Oral metronidazole was associated with significantly less pain and analgesia consumption than the placebo group. Return to work or to normal activity in the metronidazole group was also significantly earlier than in the placebo group
Balfour et al., 2002(22)	Haemorrhoidectomy	Oral	Placebo	The use of oral metronidazole did not reduce postoperative pain.
Nicolson, T., and Armstrong, D., 2004(24)	Haemorrhoidectomy	Topical	Placebo	Topical metronidazole significantly reduced pain post hemorrhoidectomy at days 7 and 14 postoperatively. Postoperative edema was reduced and overall healing was improved, compared to that of placebo.
Ala, S. et al., 2008(23)	Haemorrhoidectomy	Topical	Placebo	Topical metronidazole significantly reduced post-hemorrhoidectomy discomfort, defecation pain and narcotic consumption as compared to that of placebo group
lopez et al., 2015(20)	hemorrhoidectomy	Oral	Placebo	Metronidazole was effective in pain management after hemorrhoidectomy in comparison to the placebo with less need of rescue analgesia.
Shamsa., 2015(28)	Haemorrhoidectomy And fistulectomy	Topical	Placebo	Topical metronidazole was effective in reducing post-operative pain in anal surgeries, reducing on-defecation pain, decreasing analgesic requirements.
Lyons et al 2017(30)	haemorrhoidectomy	Topical and oral	Placebo	Metronidazole reduced postoperative pain following hemorrhoidectomy and pain on first defecation more than placebo
Neogi et al., 2018(26)	hemorrhoidectomy	Topical & oral	Placebo	Metronidazole in the form of oral or topical preparation resulted in better pain relief and less use of analgesic drugs postoperatively and therefore could correlate to earlier return to daily life activities as compared to its administration as preoperative antibiotic
Angelina et al., 2019(31)	Haemorrhoidectomy	Oral	Placebo	There was reduction in VAS score across all time points whereas there was no difference in return to work and normal daily activities and analgesia consumption between the oral metronidazole and control groups
Abbas et al., 2020(27)	Haemorrhoidectomy	Topical	Oral metronidazole	The mean pain score after topical metronidazole is less than oral metronidazole
